## Results of Experiments

---

### Structure of Experiments

A structured approach was developed to evaluate distinct dimensions affecting summarization quality, computational efficiency, and ultimately privacy risk. All combinations of factors and replications of experiments with similar parameters would all use the same train-validation-test splits (70%-15%-15%), ensuring that hyperparameter tuning is performed using validation sets, while final model evaluation occurs exclusively on the test set.

### STEP 1A: PREPROCESSING & DATA EXTRACTION

The experiment was initially set up by conducting preprocessing and data extraction work:

- All downloaded PDF files were evaluated for duplication and all file names were standardized with the following formats: “<record category>-dd-mm-yyyy.pdf”
  - Elimination of duplicates reduced total files from 1180 to 1167 PDFs.
- All text from PDFs along the file metadata were extracted into a CSV file with the following attributes:
  - File name
  - File category
  - File Date
  - Extracted Text

### STEP 1B: ESTABLISHING DEFINITION OF PII & PROXY RISK SCORES

For the purposes of assessing privacy risk for this experiment, Named Entity Recognition (NER) was used to form the foundation of what would be defined as Personally Identifiable Information. Based on the types of NER that could be classified, the following data classification was selected to define PII:

## Literature Review: Protecting PII in Abstractive Summaries using LLMs

- PERSON (names)
- ORG (names of organizations and corporations)
- NORP (nationalities, religions and political groups)
- FAC (facilities such as buildings and civic addresses)

Given the nature of the dataset, attributes such as identifying dates would not be associated with personally identifiable information as dates were largely about council dates or planned events.

Prior to training on the LLM models, a proxy definition of risk was developed to help quantify and inform the need to filter and drop data from training sets.

The formula used to define risk in a document was as follows:

$$\text{risk\_score} = (\text{num\_PERSON} + \text{num\_ORG} + \text{num\_NORP} + \text{num\_FAC}) / \text{token\_count}$$

Using this definition of risk, unique scores per file and average scores per file category could be calculated.

### STEP 1C: TRAIN-TEST-VALIDATION SPLIT & CANARIES

Prior to training the Llama 3.1b, the dataset was split into a train-test-validation by the ration of 70%-15%-15% which equaled train set of 816 files, validation set of 175 files and a test set of 176 files.

Finally, 100 canaries were generated and inserted into the training set. For canaries please see canaries.csv on the GitHub repository as well as shown below in Appendix A.

### RESOURCES for STEP 1

- All python scripts and csv files used to complete Step 1, along with copies of the PDFs from the dataset, can be found on the GitHub repository.

### STEP 2: Llama Model & Factoral Experiment Design

This experiment leverages the Llama 3.1b model, which is available here:

<https://huggingface.co/meta-llama/Llama-3.1-8B>

Once access has been granted through HuggingFace, a token was added to the environment to allow the model to access the LLM.

Please see python scripts load\_llama\_lora.py and test-llama\_lora.py on the GitHub for further details.

## Literature Review: Protecting PII in Abstractive Summaries using LLMs

Setting 'pad_token_id' to 'eos_token_id':128001 for open-end generation.  
Hello Whitby! We are thrilled to be back in Whitby for the 2019 Whitby Ribfest & Water
```

In terms of the factorial design, the original intention was to run an experiment across all combinations of the following factors:

- 3 LoRA ranks ×
- 3 learning rates ×
- 3 retrieval doc counts ×
- 3 ES thresholds ×
- 2 DPDD toggles ×
- 3 doc lengths ×
- 3 year groups ×
- 3 replications

= 4,374 total runs

Due to the computational demands running an experiment with 4,374 runs, the experiment parameters were refined to the following conditions:

- LoRA rank: 2 levels (e.g., 4, 8)
- Learning rate: 2 levels (e.g., 1e-4, 3e-4)
- Retrieval docs: fixed at 3
- Elastic threshold: fixed at 0.5
- Year group: 3 levels (pre-2018, 2018–2022, post-2022)
- Replications: 2

- Epochs: 2

For a total of 24 runs. After completion, DPDD scoring and data dropping would be conducted on a same of the 24 possible combinations (threshold of 0.1 for light to moderate removal of data) in order to compare the baseline (where memorization, or DPDD scores would be expected to increase with training) to the results where high risk data was dropped from the training data.

Finally, the Canary Extraction Success Rate, along with ROUGE, BERTScore, Precision and Recall were calculated for both the baseline dataset and the DPDD filtered results.

### **Conclusions and Recommendations**

Out of all the exploratory analysis conducted, it was surprising to see how clearly the baselining experiment showed the trend that with each epoch, total loss decreased each time which demonstrated that the model was learning. However, this came at the expense of increasing DPDD scores with each epoch, underlying the LLMs tendency to increase memorization and the likely hood for privacy breaches.

While additional exploratory analysis can be found on the GitHub, including tables and graphs comparing the baselining dataset to the DPDD filtered results, the initial baselining does confirm overall risk to privacy when using LLMs to generate abstractive summaries. When comparing to the DPDD filtered results, CESR scores show an improvement to prevent privacy breaches, however the table below underscores the fundamental issue of the LLM memorizing unique details that exists with or without the DPDD mechanism.

**Table 3: First 5 Runs of the Baseline Factorial Experiment with 24 Combinations.**
